# Embedded System Hardware

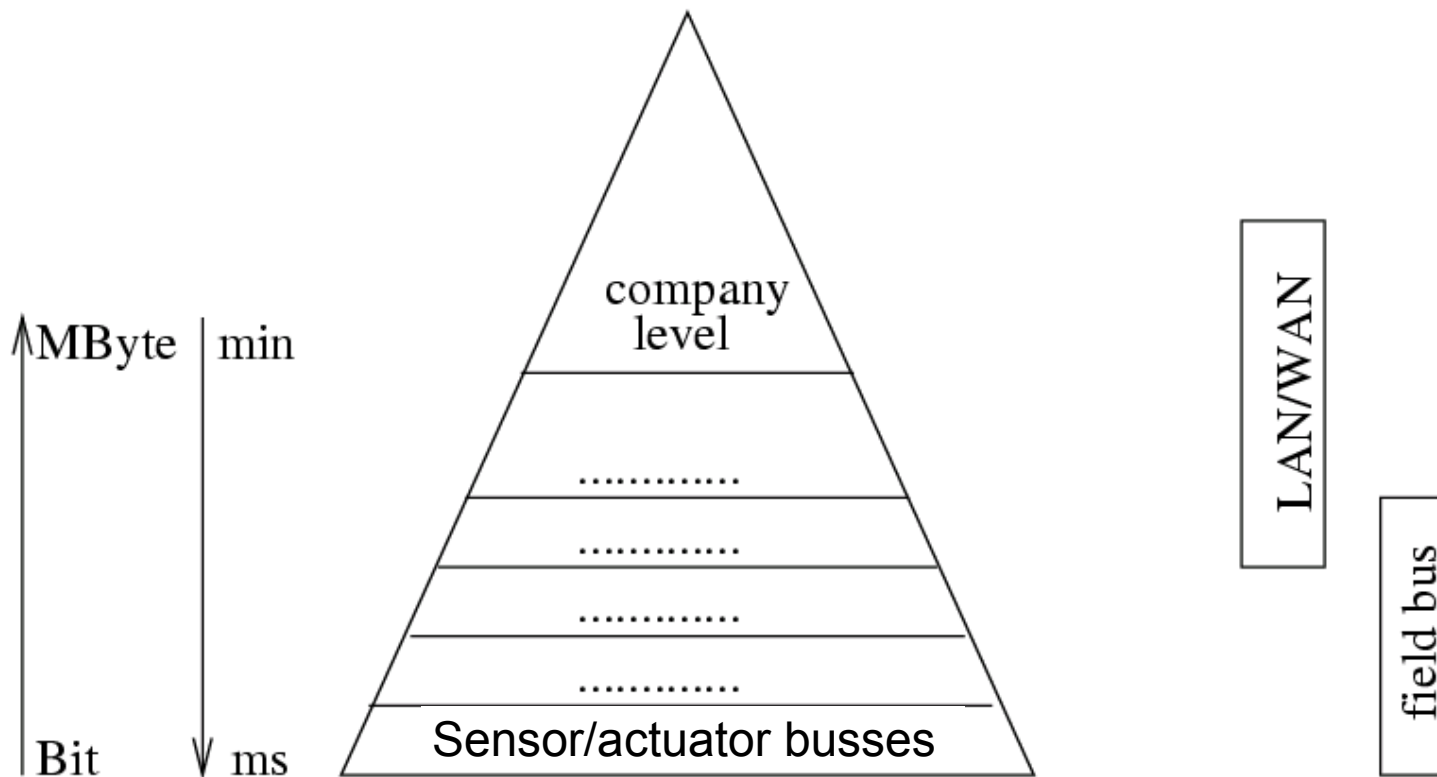

Embedded system hardware is frequently used in a loop (*“hardware in a loop”*):

👉 cyber-physical systems

# Communication: Hierarchy

Inverse relation between volume and urgency quite common:

# Communication - Requirements -

- Real-time behavior
- Efficient, economical  
(e.g. centralized power supply)
- Appropriate bandwidth and communication delay
- Robustness
- Fault tolerance
- Maintainability
- Diagnosability
- Security
- Safety

# Basic techniques: Electrical robustness

## Single-ended vs. differential signals

Voltage at input of Op-Amp positive  $\rightarrow$  '1'; otherwise  $\rightarrow$  '0'

Combined with twisted pairs; Most noise added to both wires.

# Evaluation

---

## Advantages:

- Subtraction removes most of the noise
- Changes of voltage levels have no effect
- Reduced importance of ground wiring
- Higher speed

## Disadvantages:

- Requires negative voltages
- Increased number of wires and connectors

## Applications:

- USB, FireWire, ISDN
- Ethernet (STP/UTP CAT 5/6 cables)
- differential SCSI
- High-quality analog audio signals (XLR)

© wikipedia

# Real-time behavior

---

Carrier-sense multiple-access/collision-detection (CSMA/CD, Standard Ethernet) no guaranteed response time.

Alternatives:

- token rings, token busses
- Carrier-sense multiple-access/collision-avoidance (CSMA/CA)
  - WLAN techniques with request preceding transmission
  - Each partner gets an ID (priority). After each bus transfer, all partners try setting their ID on the bus; partners detecting higher ID disconnect themselves from the bus. Highest priority partner gets guaranteed response time; others only if they are given a chance.

# Time division multiple access (TDMA) busses

Each communication partner is assigned a fixed time slot

Example:

<http://www.ece.cmu.edu/~koopman/jtdma/jtdma.html#classical>

- Master sends sync
- Some waiting time
- Each slave transmits in its time slot
- Variations (truncating unused slots, several slots per slave) exist

# Advantages of TDMA-busses over priority-driven schemes

---

- *Provides QoS guarantees in networks on chips*
- *TDMA resources support temporal composability, by separating resource access of different subsystems*
- *TDMA resources have a very deterministic timing behavior*
- *Can be made fault tolerant*
- *Support error detection*
- *Support error contention, i.e. a faulty subsystem does not affect the correct behavior of the remaining system*
- *Often applied for single processor scheduling to enable composable and hierarchical scheduling.*
- **Example: ARM AMBA-bus**

[Ernesto Wandeler Lothar Thiele: Optimal TDMA Time Slot and Cycle Length Allocation for Hard Real-Time Systems, ASP-DAC, 2006]

# Other basic techniques

---

- **Fault tolerance:**  
error detecting and error correcting bus protocols
- **Privacy:**  
encryption, virtually private networks

# Sensor/actuator busses

1. **Sensor/actuator busses:** Real-time behavior very important; different techniques:

Many wires

less wires

expensive & flexible

# Field busses: Profibus

---

More powerful/expensive than sensor interfaces; mostly serial.  
Emphasis on transmission of small number of bytes.

Examples:

## 1. Process Field Bus (Profibus)

Designed for factory and process automation.

Focus on **safety**; comprehensive protocol mechanisms.

Claiming 20% market share for field busses.

Token passing.

≤93.75 kbit/s (1200 m); 1500 kbits/s (200m);

12 Mbit/s (100m)

Integration with Ethernet via Profinet.

[<http://www.profibus.com/>]

# Controller area network (CAN)

---

## 2. Controller area network (CAN)

- Designed by Bosch and Intel in 1981;
- used in cars and other equipment;
- differential signaling with twisted pairs,
- arbitration using CSMA/CA,
- throughput between 10kbit/s and 1 Mbit/s,
- low and high-priority signals,
- maximum latency of 134  $\mu$ s for high priority signals,
- coding of signals similar to that of serial (RS-232) lines of PCs, with modifications for differential signaling.
- See [//www.can.bosch.com](http://www.can.bosch.com)

# Time-Triggered-Protocol (TTP)

---

3. The **Time-Triggered-Protocol (TTP)** [Kopetz et al.] for fault-tolerant safety systems like airbags in cars.

- 4. FlexRay:** developed by the FlexRay consortium (BMW, Ford, Bosch, DaimlerChrysler, ...)  
Combination of a variant of the TTP and the Byteflight [Byteflight Consortium, 2003] protocol.  
Specified in SDL.

- Improved error tolerance and time-determinism
- Meets requirements with transfer rates  $\gg$  CAN std.

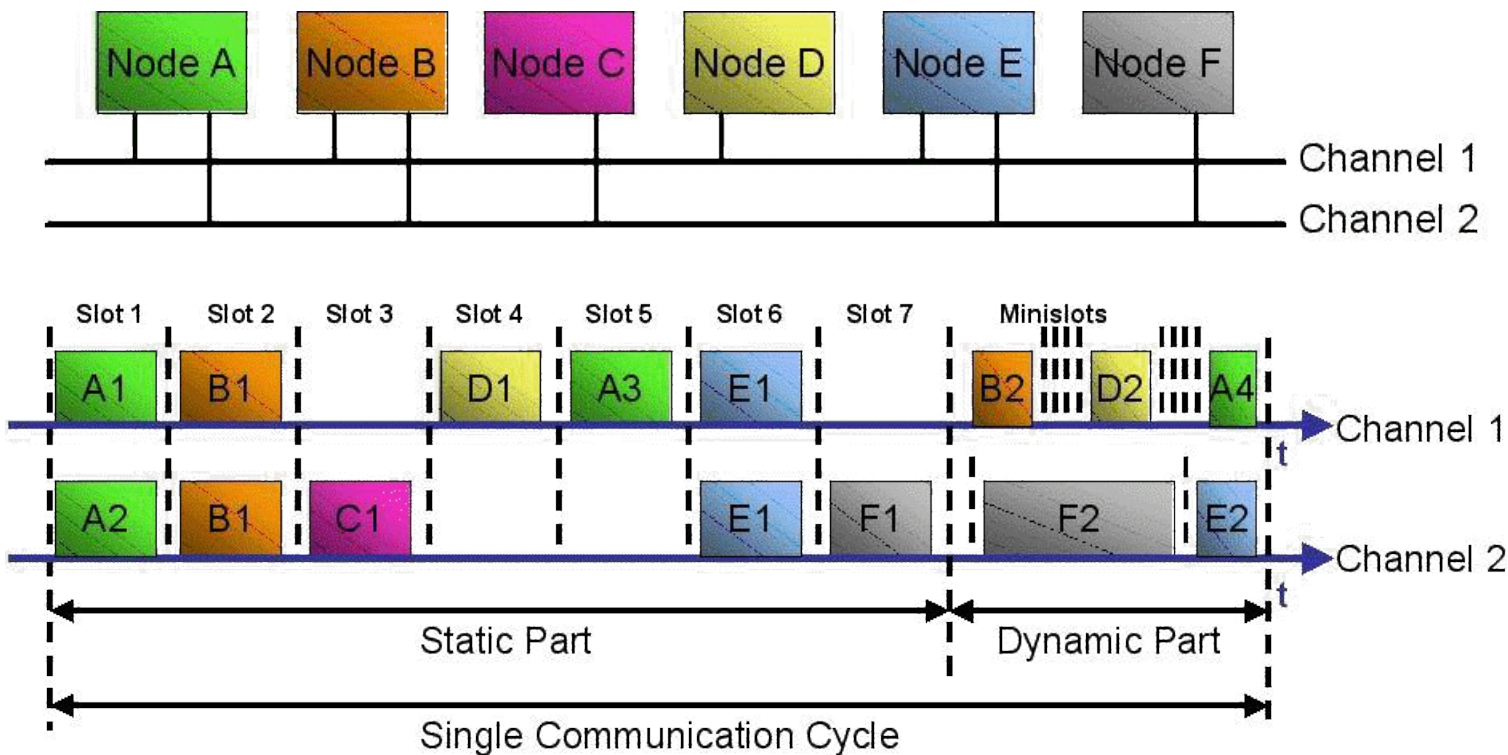

**High data rate can be achieved:**

- initially targeted for  $\sim$  10Mbit/sec;
- design allows much higher data rates
- TDMA (Time Division Multiple Access) protocol:  
Fixed time slot with exclusive access to the bus
- Cycle subdivided into a static and a dynamic segment.

# TDMA in FlexRay

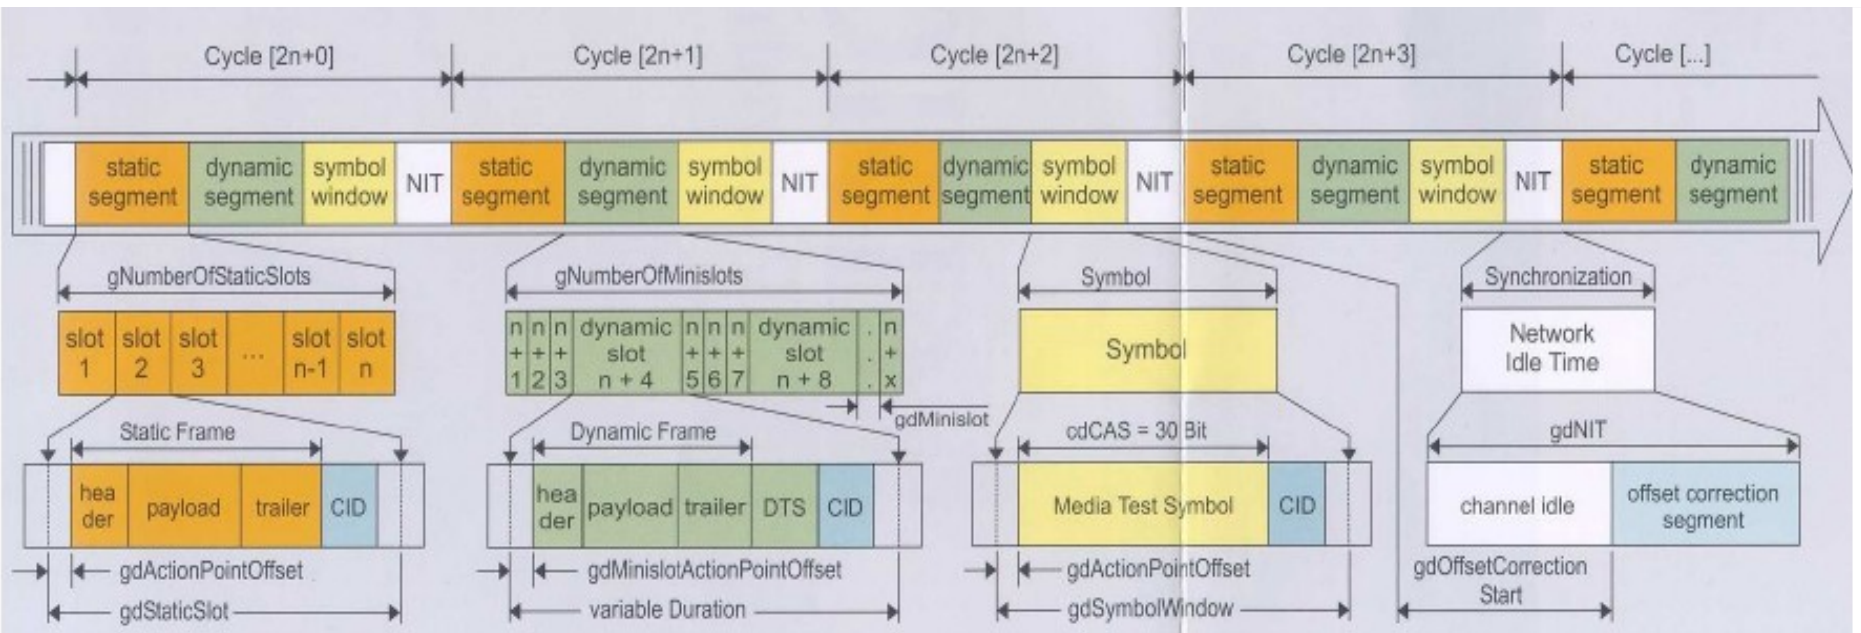

Exclusive bus access enabled for short time in each case.  
Dynamic segment for transmission of variable length information.  
Fixed priorities in dynamic segment: Minislots for each potential sender.  
Bandwidth used only when it is actually needed.

[http://www.tzm.de/FlexRay/FlexRay\\_Introduction.html](http://www.tzm.de/FlexRay/FlexRay_Introduction.html)

# Time intervals in Flexray

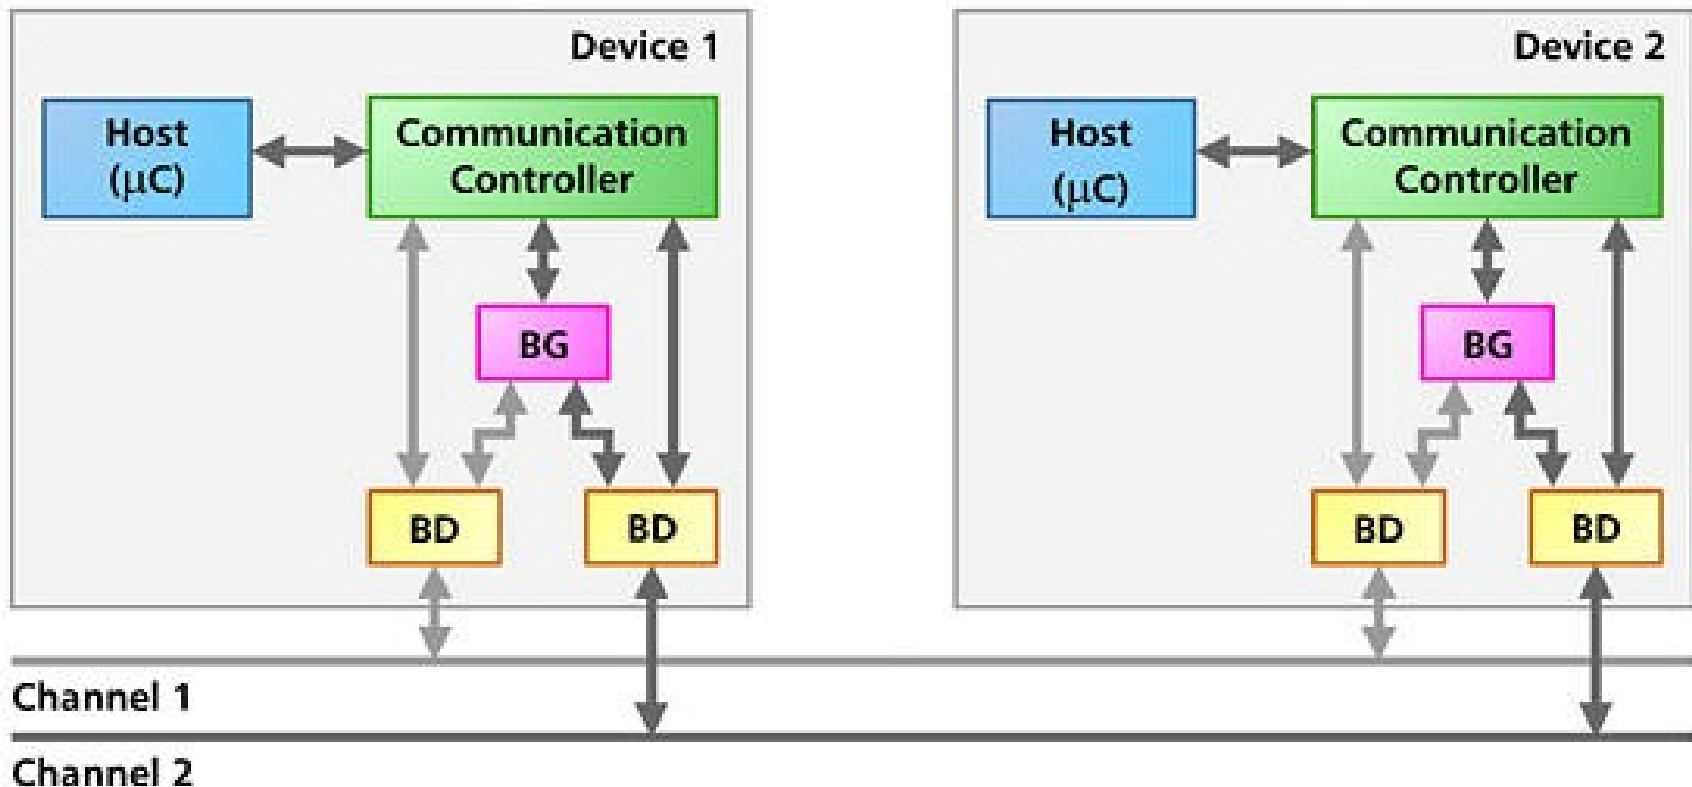

Quelle: Vector Informatik GmbH

- **Microtick ( $\mu t$ )** = Clock period in partners, may differ between partners
- **Macrotick ( $mt$ )** = Basic unit of time, synchronized between partners  
( $=r_i \times \mu t$ ,  $r_i$  varies between partners  $i$ )
- **Slot** = Interval allocated per sender in static segment ( $=p \times mt$ ,  $p$ : fixed (configurable))
- **Minislot** = Interval allocated per sender in dynamic segment ( $=q \times mt$ ,  $q$ : variable)  
Short minislot if no transmission needed; starts after previous minislot.
- **Cycle** = Static segment + dynamic segment + network idle time

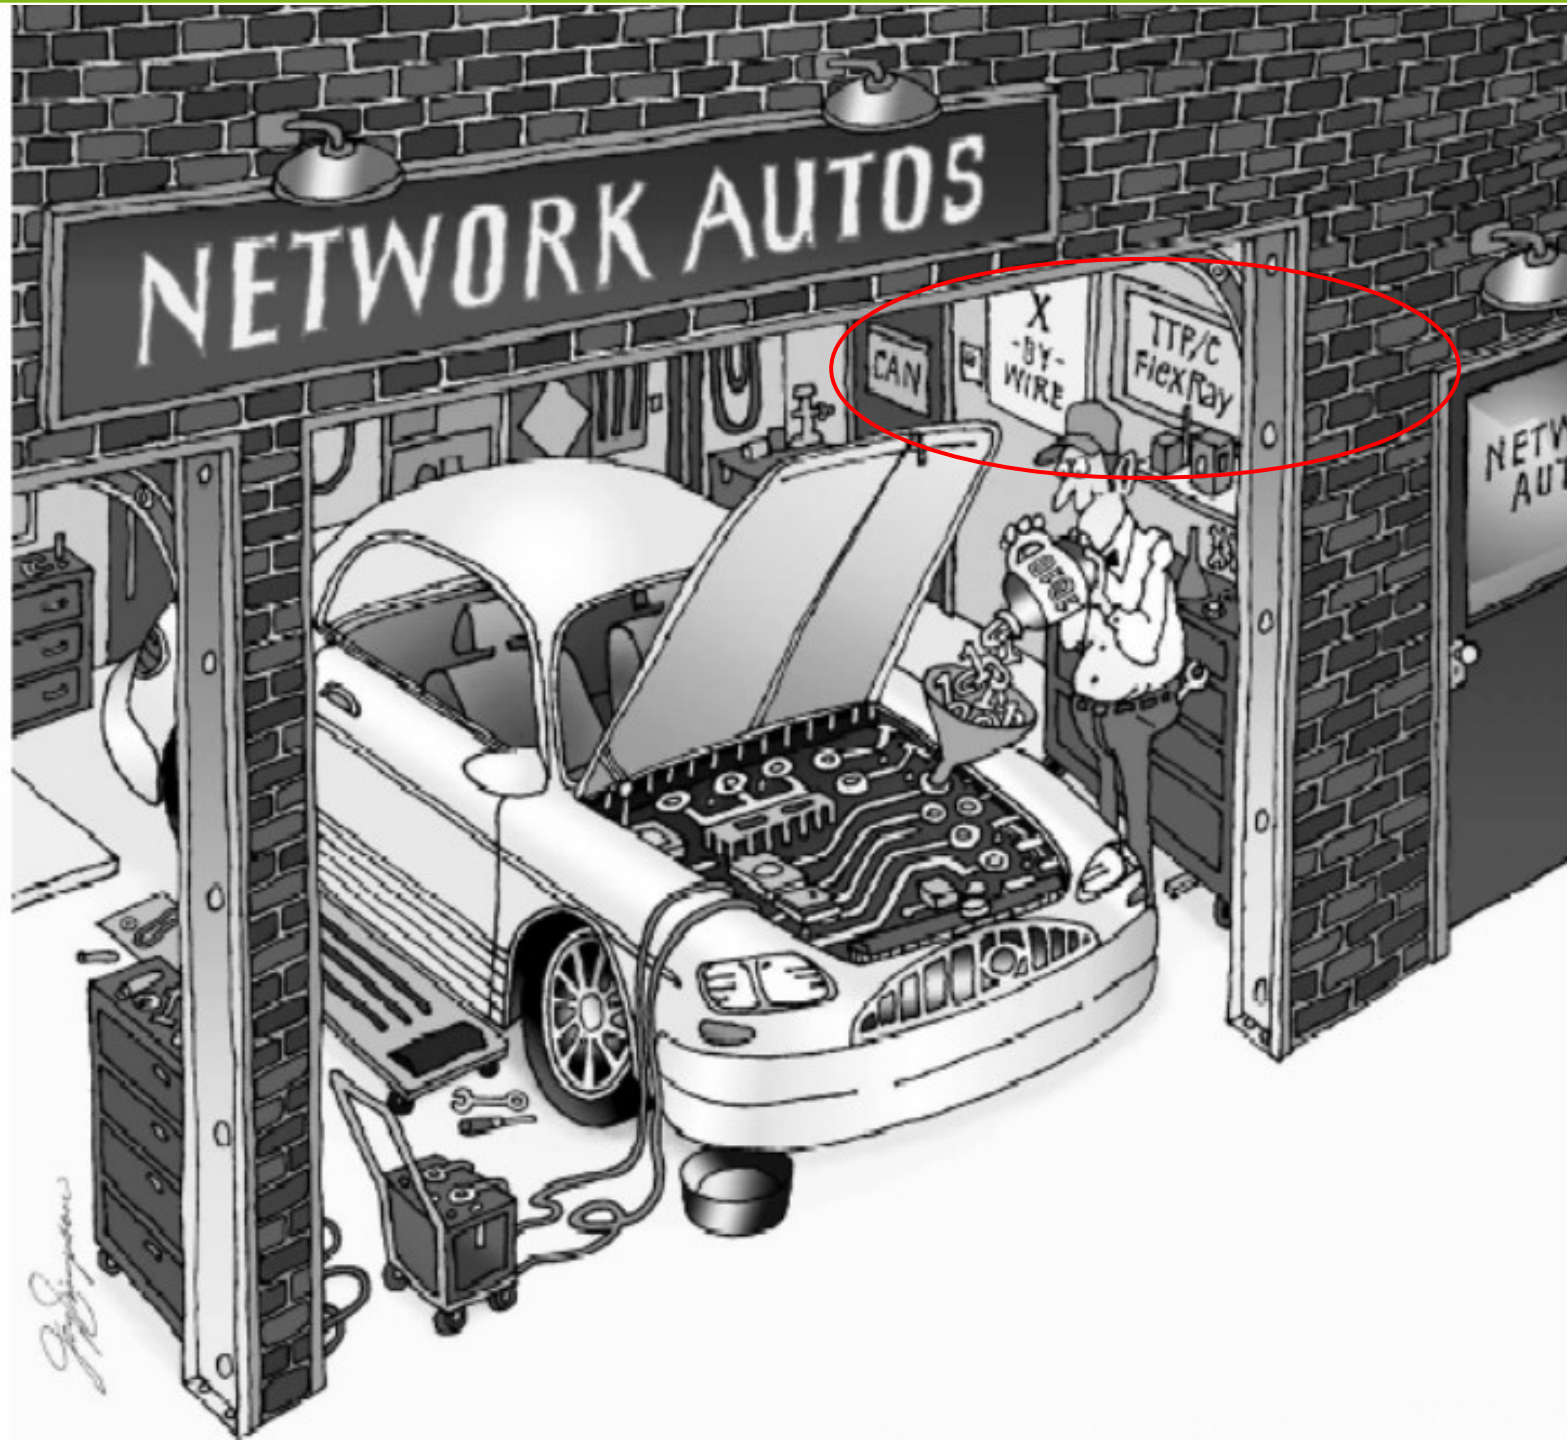

# Structure of Flexray networks

Bus guardian protects the system against failing processors, e.g. so-called “babbling idiots”

[http://www.ixxat.de/index.php?seite=introduction\\_flexray\\_en&root=5873&system\\_id=5875&com=formular\\_suche\\_treff](http://www.ixxat.de/index.php?seite=introduction_flexray_en&root=5873&system_id=5875&com=formular_suche_treff)

# Other field busses

---

- **LIN:** low cost bus for interfacing sensors/actuators in the automotive domain
- **MOST:** Multimedia bus for the automotive domain (not really a field bus)
- **MAP:**MAP is a bus designed for car factories.
- **EIB:**The European Installation Bus (EIB) is a bus designed for smart homes. **European Installation Bus (EIB)**  
Designed for smart buildings; CSMA/CA; low data rate.
- **IEEE 488:** Designed for laboratory equipment.
- Attempts to use standard Ethernet.  
However, timing predictability remains a serious issue.

# Wireless communication

*"It appears to be some new kind of wireless technology."*

© 2001 The New Yorker Collection from cartoonbank.com

# Wireless communication: Examples

---

- IEEE 802.11 a/b/g/n
- UMTS; HSPA
- DECT
- Bluetooth
- ZigBee

Timing predictability of wireless communication?

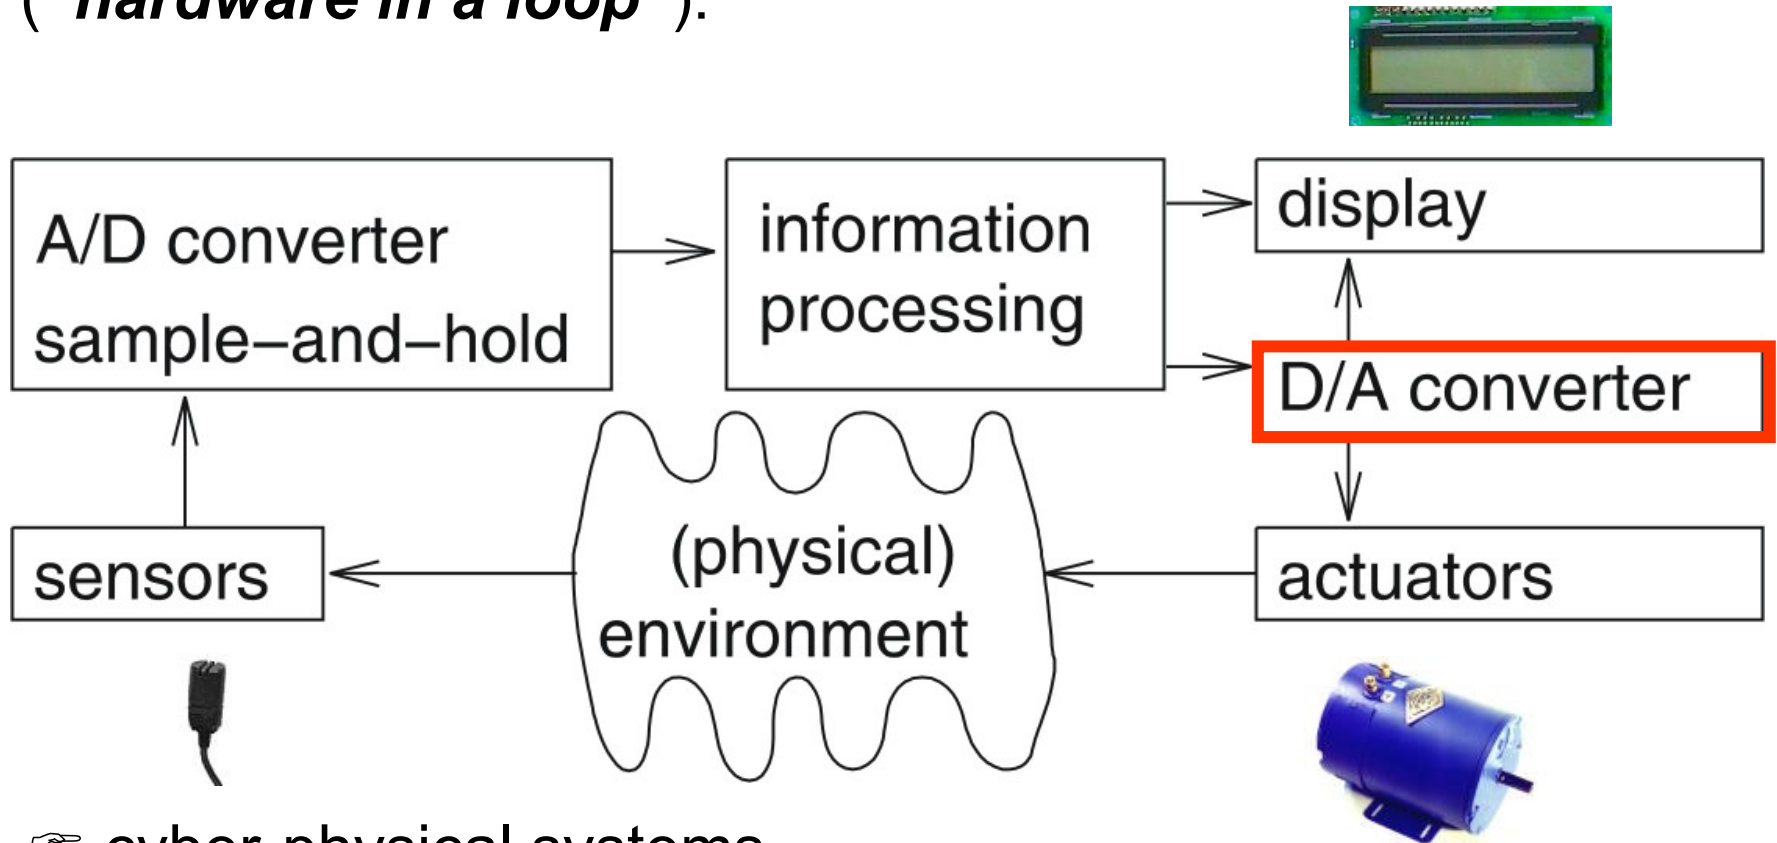

# D/A-Converters

# Embedded System Hardware

Embedded system hardware is frequently used in a loop (*“hardware in a loop”*):

👉 cyber-physical systems

# Output

Output devices of embedded systems include

- **Displays:** Display technology is extremely important. Major research and development efforts
- **Electro-mechanical devices:** these influence the environment through motors and other electro-mechanical equipment.  
Frequently require analog output.

Naming convention:

# Kirchhoff's junction rule

## Kirchhoff's Current Law, Kirchhoff's first rule

### Kirchhoff's Current Law:

At any point in an electrical circuit, the sum of currents flowing towards that point is equal to the sum of currents flowing away from that point.

(Principle of conservation of electric charge)

Formally, for any node in a circuit:

$$\sum_k i_k = 0$$

Count current flowing away from node as negative.

Example:

$$i_1 + i_2 + i_4 = i_3$$

$$i_1 + i_2 - i_3 + i_4 = 0$$

[Jewett and Serway, 2007].

# Kirchhoff's loop rule

## Kirchhoff's Voltage Law, Kirchhoff's second rule

The principle of conservation of energy implies that:

The sum of the potential differences (voltages) across all elements around any closed circuit must be zero

[Jewett and Serway, 2007].

Formally, for any loop in a circuit:

$$\sum_k V_k = 0$$

Count voltages traversed against arrow direction as negative

Example:

$$V_1 + V_2 - V_3 - V_4 = 0$$

$V_3 = R_3 \times I$  if current counted in the same direction as  $V_3$

$V_3 = -R_3 \times I$  if current counted in the opposite direction as  $V_3$

# Operational Amplifiers (Op-Amps)

Operational amplifiers (op-amps) are devices amplifying the voltage difference between two input terminals by a large gain factor  $g$

$$V_{\text{out}} = (V_+ - V_-) \cdot g$$

High impedance input terminals  
 $\Rightarrow$  Currents into inputs  $\approx 0$

Op-amp in a separate package  
(TO-5) [wikipedia]

For an **ideal** op-amp:  $g \rightarrow \infty$

(In practice:  $g$  may be around  $10^4..10^6$ )

# Op-Amps with feedback

In circuits, negative feedback is used to define the actual gain

Due to the feedback to the *inverted* input,  $R_1$  reduces voltage  $V_-$ . To which level?

$$V_{\text{out}} = -g \cdot V_- \quad (\text{op-amp feature})$$

$$I \cdot R_1 + V_{\text{out}} - V_- = 0 \quad (\text{loop rule})$$

$$\Rightarrow I \cdot R_1 + -g \cdot V_- - V_- = 0$$

$$\Rightarrow (1+g) \cdot V_- = I \cdot R_1$$

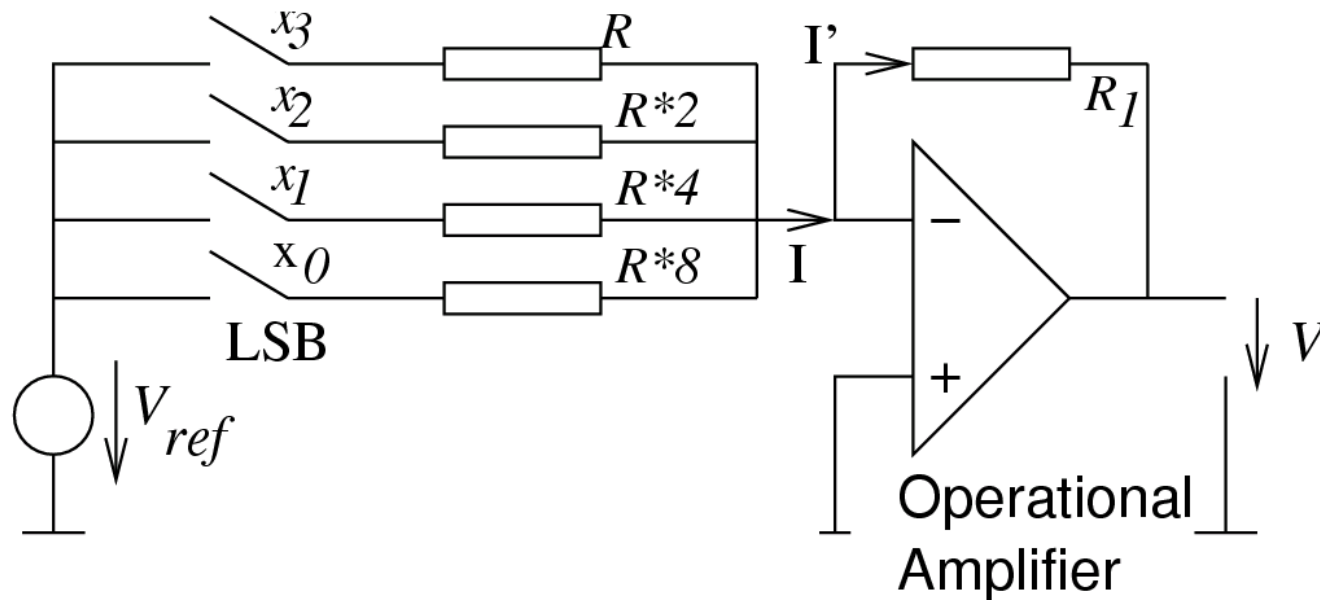

$$\Rightarrow V_- = \frac{I \cdot R_1}{1+g}$$

$$V_{-,ideal} = \lim_{g \rightarrow \infty} \frac{I \cdot R_1}{1+g} = 0$$

$V_-$  is called **virtual ground**: the voltage is 0, but the terminal may not be connected to ground

# Digital-to-Analog (D/A) Converters

Various types, can be quite simple,  
e.g.:

# Output voltage ~ no. represented by x

Junction rule:  $I = \sum_i I_i$

Loop rule:  $I_i = x_i \times \frac{V_{ref}}{2^{3-i} \times R}$

☞  $I = x_3 \times \frac{V_{ref}}{R} + x_2 \times \frac{V_{ref}}{2 \times R} + x_1 \times \frac{V_{ref}}{4 \times R} + x_0 \times \frac{V_{ref}}{8 \times R} = \frac{V_{ref}}{8 \times R} \times \sum_{i=0}^3 x_i \times 2^i$

Loop rule\*:  $V + R_1 \times I' = 0$

Junction rule<sup>o</sup>:  $I = I'$

Hence:  $V + R_1 \times I = 0$

Finally:  $-V = V_{ref} \times \frac{R_1}{8 \times R} \sum_{i=0}^3 x_i \times 2^i = V_{ref} \times \frac{R_1}{8 \times R} \times nat(x)$

$I \sim nat(x)$ , where  $nat(x)$ : natural number represented by  $x$ ;

Op-amp turns current  $I \sim nat(x)$  into a voltage  $\sim nat(x)$

# Output generated from signal $e_3(t)$

Assuming  
“zero-order  
hold”

Possible to  
reconstruct  
input  
signal?

# Sampling Theorem

Peter Marwedel  
Informatik 12  
TU Dortmund  
Germany

# Possible to reconstruct input signal?

- Necessary condition: Nyquist criterion met
- Let  $\{t_s\}$ ,  $s = \dots, -1, 0, 1, 2, \dots$  be times at which we sample  $g(t)$
- Assume a constant sampling rate of  $1/T_s$  ( $\forall s: T_s = t_{s+1} - t_s$ ).
- According sampling theory, we can approximate the input signal as follows:

$$z(t) = \sum_{s=-\infty}^{\infty} \frac{y(t_s) \sin \frac{\pi}{T_s} (t - t_s)}{\frac{\pi}{T_s} (t - t_s)}$$

Weighting factor  
for influence of  
 $y(t_s)$  at time  $t$

[Oppenheim, Schaffer, 2009]

# Weighting factor for influence of $y(t_s)$ at time $t$

$$\text{sinc}(t - t_s) = \frac{\sin\left(\frac{\pi}{T_s}(t - t_s)\right)}{\frac{\pi}{T_s}(t - t_s)}$$

# Contributions from the various sampling instances

# (Attempted) reconstruction of input signal

# How to compute the *sinc*( ) function?

$$z(t) = \sum_{s=-\infty}^{\infty} \frac{y(t_s) \sin \frac{\pi}{T_s} (t - t_s)}{\frac{\pi}{T_s} (t - t_s)}$$

- **Filter theory:** The required interpolation is performed by an ideal low-pass filter (*sinc* is the Fourier transform of the low-pass filter transfer function)

Filter removes high frequencies present the step function  $y(t)$

# How precisely are we reconstructing the input?

---

$$z(t) = \sum_{s=-\infty}^{\infty} \frac{y(t_s) \sin \frac{\pi}{T_s} (t - t_s)}{\frac{\pi}{T_s} (t - t_s)}$$

- **Sampling theory:**

- **Reconstruction using *sinc* () is precise**

- However, it may be impossible to really compute  $z(t)$  as indicated ....

# Limitations

---

$$z(t) = \sum_{s=-\infty}^{\infty} \frac{y(t_s) \sin \frac{\pi}{T_s} (t - t_s)}{\frac{\pi}{T_s} (t - t_s)}$$

- Actual filters do not compute  $\text{sinc}(\ )$   
In practice, filters are used as an approximation.  
Computing good filters is an art itself!
- All samples must be known to reconstruct  $e(t)$  or  $g(t)$ .  
☞ Waiting indefinitely before we can generate output!  
In practice, only a finite set of samples is available.
- Actual signals are never perfectly bandwidth limited.
- Quantization noise cannot be removed.

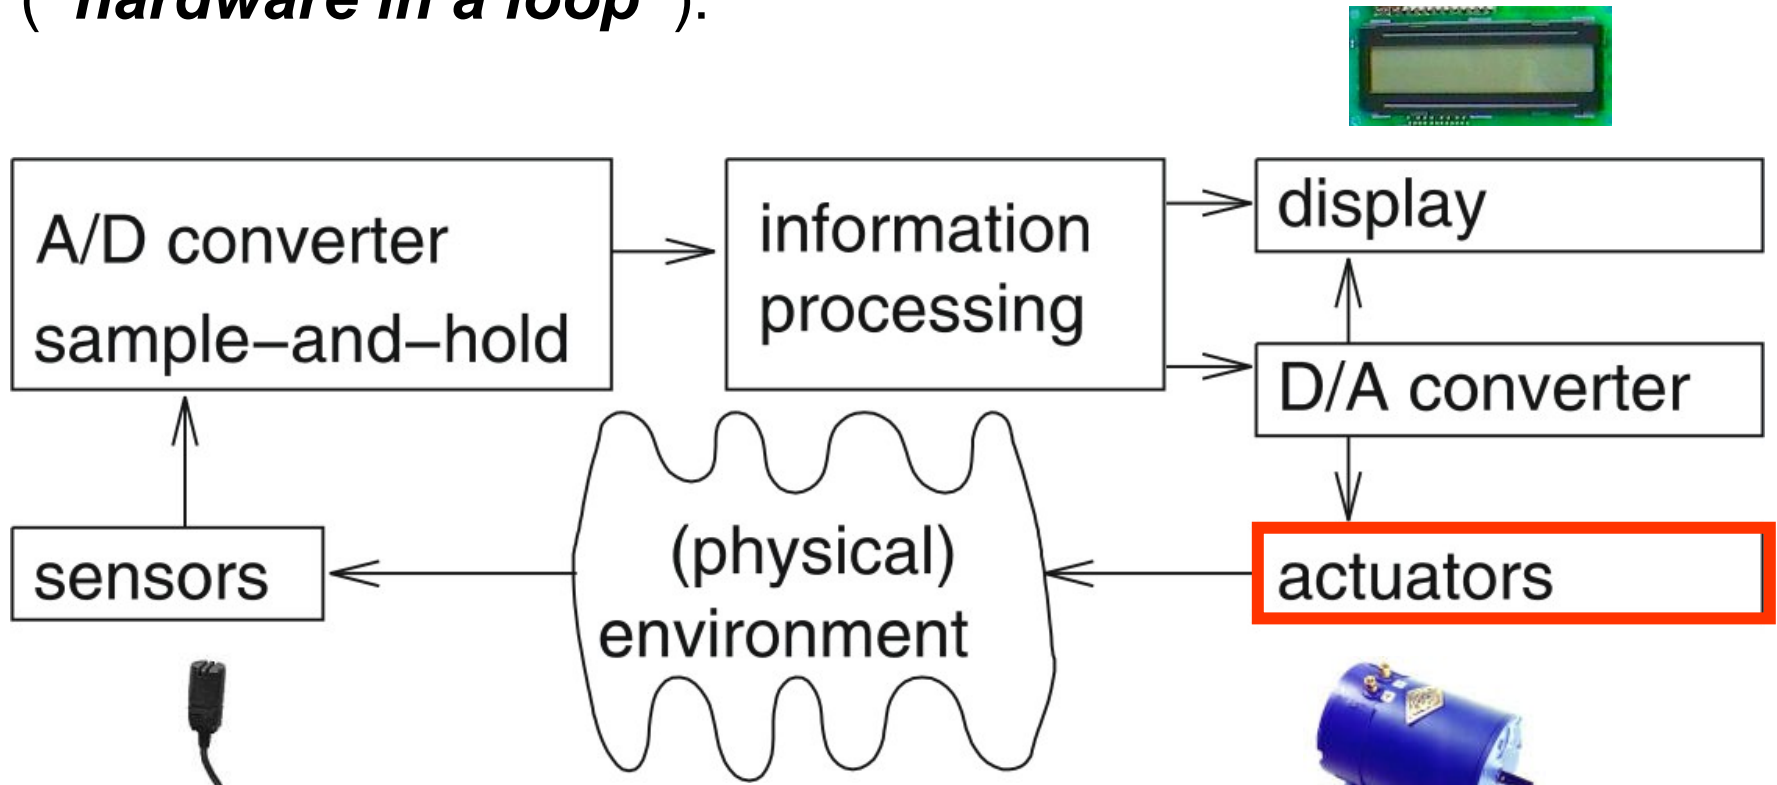

# Actuators

Peter Marwedel  
Informatik 12  
TU Dortmund  
Germany

# Embedded System Hardware

Embedded system hardware is frequently used in a loop (*“hardware in a loop”*):

👉 cyber-physical systems

# Actuators

---

Huge variety of actuators and output devices,  
impossible to present all of them.

Microsystems motors as examples (© MCNC):

# Stepper Motor

---

- Stepper motor: rotates fixed number of degrees when given a “step” signal.
- In contrast, DC motor just rotates when power applied.
- Rotation achieved by applying specific voltage sequence to coils
- Controller greatly simplifies this

<http://www.cise.ufl.edu/~prabhat/Teaching/cis6930-f04/comp4.pdf>

# Secure Hardware

---

- Security needed for communication and storage
- Demand for special equipment for cryptographic keys
- To resist side-channel attacks like
  - measurements of the supply current or
  - Electromagnetic radiation.

Special mechanisms for physical protection (shielding, sensor detecting tampering with the modules).

- Logical security, using cryptographic methods needed.
- Smart cards: special case of secure hardware
  - Have to run with a very small amount of energy.
- In general, we have to distinguish between different levels of security and knowledge of “adversaries”

# Summary

---

## Hardware in a loop

- Sensors
- Discretization
- Information processing
  - Importance of energy efficiency
  - Special purpose HW very expensive
