Models of computation considered in this course

Communication/ local computations	Shared memory	Message passing	
		Synchronous	Asynchronous
Undefined components		Plain text, use cases (Message) sequence charts	
Communicating finite state machines	StateCharts		SDL
Data flow	Scoreboarding + Tomasulo Algorithm (☞ Comp.Archict.)		Kahn networks, SDF
Petri nets		C/E nets, P/T nets, ...	
Discrete event (DE) model	VHDL*, Verilog*, SystemC*, ...	Only experimental systems, e.g. distributed DE in Ptolemy	
Von Neumann model	C, C++, Java	C, C++, Java with libraries CSP, ADA	

Discrete event semantics

Basic discrete event (DE) semantics

- Queue of future actions, sorted by time
- Loop:
 - Fetch next entry from queue
 - Perform function as listed in entry
 - May include generation of new entries
- Until termination criterion = true

HDLs using discrete event (DE) semantics

Used in hardware description languages (HDLs):
Description of concurrency is a must for HW description languages!

- Many HW components are operating concurrently
- Typically mapped to “processes“
- These processes communicate via “signals“
- Examples:
 - MIMOLA [Zimmermann/Marwedel], ~1975 ...
 -
 - VHDL (very prominent example in DE modeling)
One of the 3 most important HDLs:
VHDL, Verilog, SystemC

VHDL

VHDL = VHSIC hardware description language

VHSIC = very high speed integrated circuit

1980: Def. started by US Dept. of Defense (DoD) in 1980

1984: first version of the language defined, based on ADA
(which in turn is based on PASCAL)

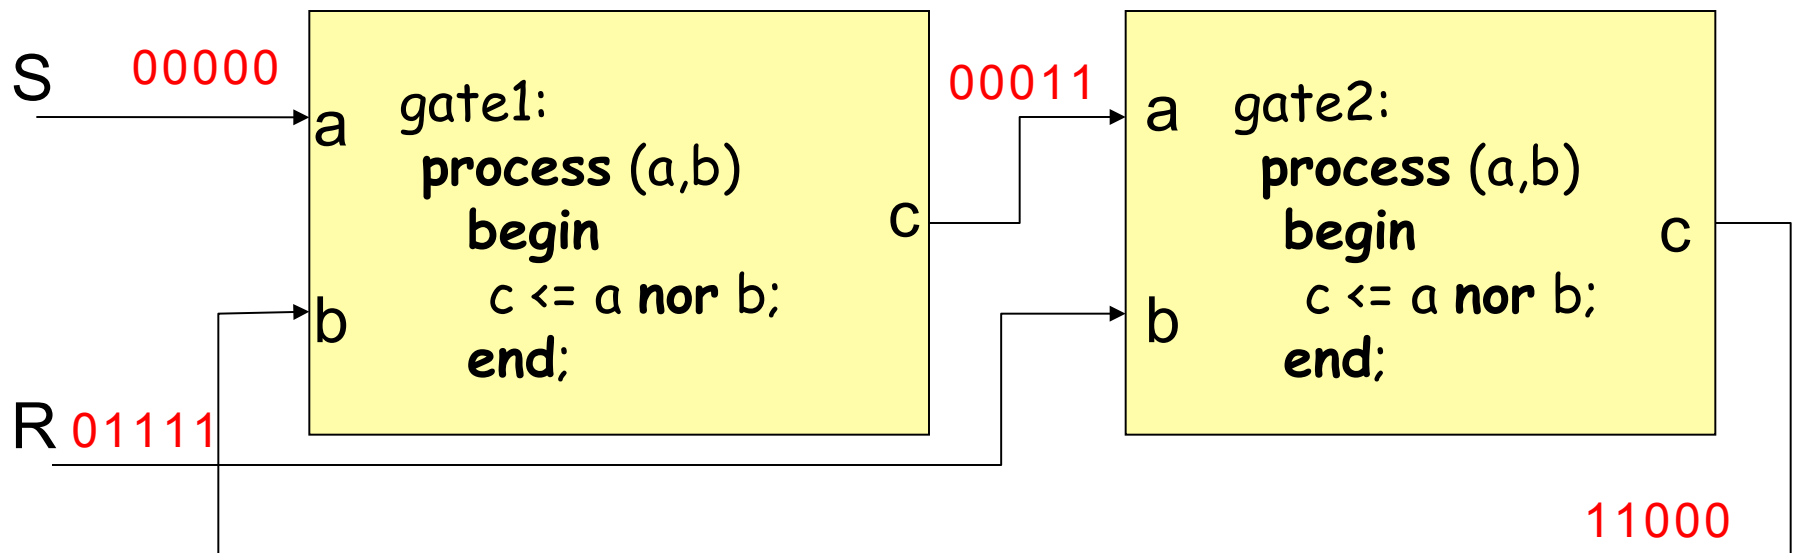

1987: revised version became IEEE standard 1076

1992: revised IEEE standard

1999: VHDL-AMS: includes analog modeling

2006: Major extensions

Simple example (VHDL notation)

Processes will wait for changes on their input ports.

If they arrive, processes will wake up, compute their code and deposit changes of output signals in the event queue and wait for the next event.

If all processes wait, the next entry will be taken from the event queue.

VHDL processes

Delays allowed:

```
process (a,b)
begin
  c <= a nor b after 10 ns;
end;
```

Equivalent to

```
process
begin
  c <= a nor b after 10 ns;
  wait on a,b;
end;
```

- <=: signal assignment operator
- Each executed signal assignment will result in **adding** entries in the projected waveform, as indicated by the (optional) delay time
- Implicit loop around the code in the body
- Sensitivity lists are a shorthand for a single **wait on**-statement at the end of the process body

The full adder as an example

entity full_adder is

```
port(a, b, carry_in: in Bit; -- input ports
      sum,carry_out: out Bit); --output ports
end full_adder;
```

architecture behavior of full_adder is
begin

```
sum      <= (a xor b) xor carry_in after 10 ns;
carry_out <= (a and b) or (a and carry_in) or
             (b and carry_in)      after 10 ns;
```

end behavior;

The full adder as an example

- Simulation results -

VHDL semantics: global control

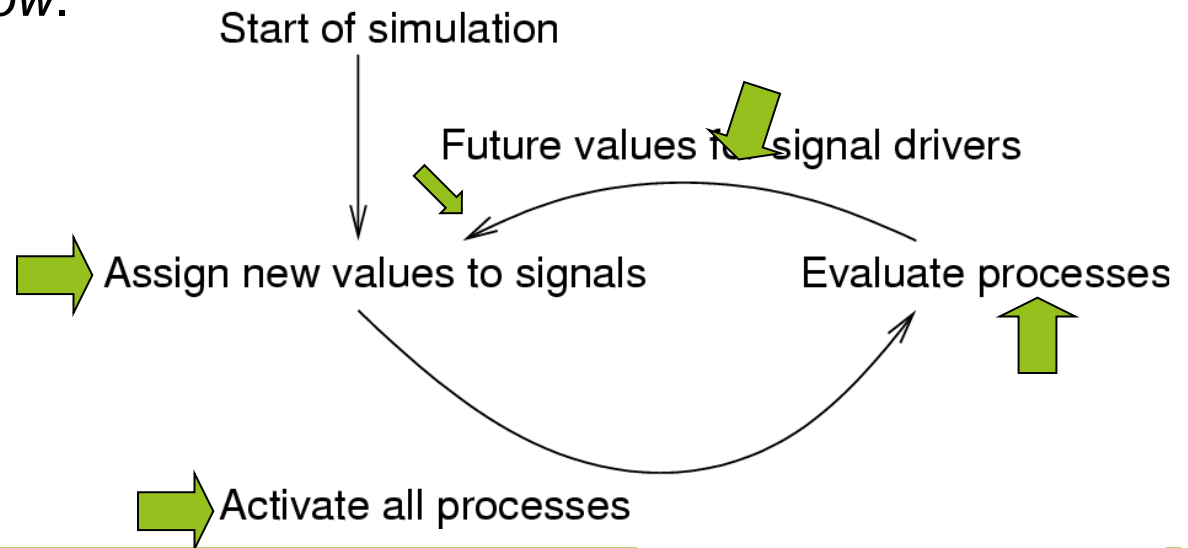

According to the original VHDL standards document:

- The execution of a model consists of an initialization phase followed by the repetitive execution of process statements in the description of that model.
- Initialization phase executes each process once.

VHDL semantics: initialization

At the beginning of initialization, the current time, T_c is 0 ns.

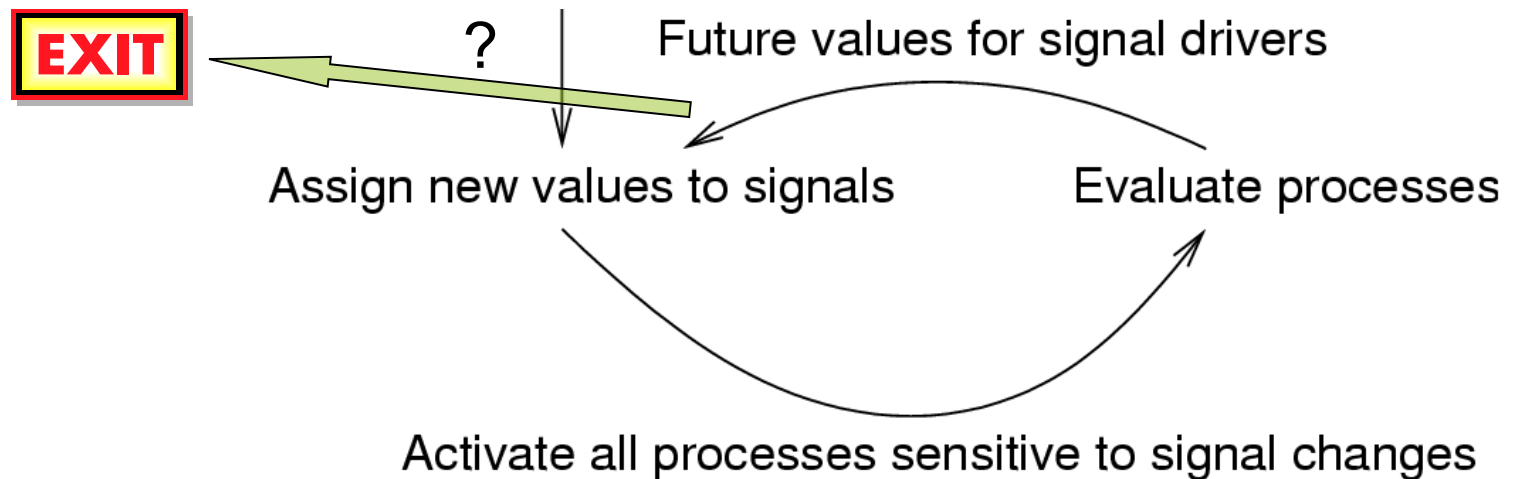

- ➔ The ... effective value of each explicitly declared signal are computed, and the current value of the signal is set to the effective value. ...
- ➔ Each ... process ... is executed until it suspends.
- ➔ The time of the next simulation cycle (... in this case ... the 1st cycle), T_n is calculated according to the rules of step *f* of the simulation cycle, below.

VHDL semantics: The simulation cycle (1)

According to the standard, the simulation cycle is as follows:

- a) Stop if $T_n = \text{time}'\text{high}$
and “nothing else is to be done” at T_n .
The current time, T_c is set to T_n .

VHDL semantics: The simulation cycle (2)

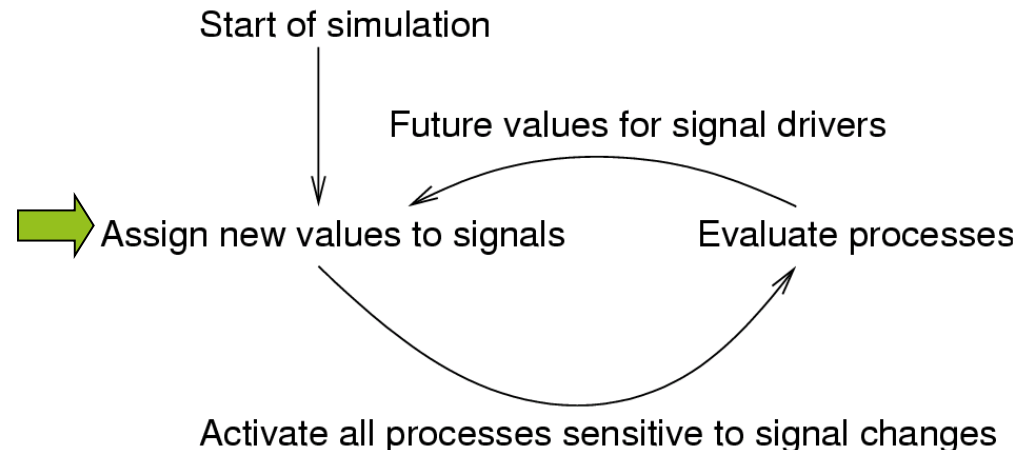

- a) ***Each active explicit signal in the model is updated. (Events may occur as a result.)***

Previously computed entries in the queue are now assigned if their time corresponds to the current time T_c .

New values of signals are not assigned before the next simulation cycle, at the earliest.

Signal value changes result in events  enable the execution of processes that are sensitive to that signal.

- b) ..

VHDL semantics: The simulation cycle (3)

- a) $\forall P$ sensitive to s : if event on s in current cycle: P resumes.
- b) Each ... process that has resumed in the current simulation cycle is executed until it suspends*.

*Generates future values for signal drivers.

VHDL semantics: The simulation cycle (4)

- a) Time T_n of the next simulation cycle = earliest of
1. time 'high (end of simulation time).
 2. The next time at which a driver becomes active
 3. The next time at which a process resumes (determined by **wait for** statements).

Next simulation cycle (if any) will be a delta cycle if $T_n = T_c$.

δ -simulation cycles

...
Next simulation cycle (if any) will be a delta cycle if $T_n = T_c$.
Delta cycles are generated for delay-less models.
There is an arbitrary number of δ cycles between any 2 physical time instants:

In fact, simulation of delay-less hardware loops might not terminate (don't even advance T_c).

δ -simulation cycles

Simulation of an RS-Flipflop

	0ns	0ns+ δ	0ns+2 δ	0ns+3 δ
R	1	1	1	1
S	0	0	0	0
Q	1	0	0	0
nQ	0	0	1	1

```

gate1:
  process (S,Q)
  begin
    nQ <= S nor Q;
  end;
gate2:
  process (R,nQ)
  begin
    Q <= R nor nQ;
  end;
  
```

δ cycles reflect the fact that no real gate comes with zero delay.

☞ should delay-less signal assignments be allowed at all?

δ -simulation cycles and determinate simulation semantics

Semantics of

$a \leq b$;

$b \leq a$; ?

Separation into 2 simulation phases results in determinate semantics (☞ StateMate).

Multi-valued logic and standard IEEE 1164

Abstraction of electrical signals

- Complete analog simulation at the circuit level would be time-consuming
- ☞ We try to use digital values and DE simulation as long as possible
- ☞ However, using just 2 digital values would be too restrictive (as we will see)

How many logic values for modeling ?

Two ('0' and '1') or more?

If real circuits have to be described, some abstraction of the driving strength is required.

☞ We introduce the distinction between:

- the **logic level** (as an abstraction of the voltage) and
- the **strength** (as an abstraction of the current drive capability) of a signal.

The two are encoded in **logic values**.

☞ CSA (connector, switch, attenuator) - theory [Hayes]

1 signal strength

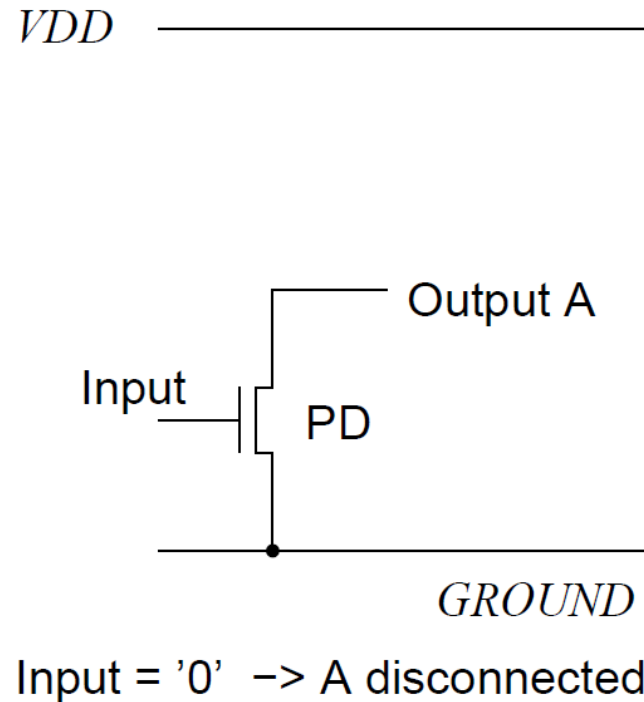

Logic values '0' and '1'.

Both of the same strength.

Encoding false and true, respectively.

2 signal strengths

Many subcircuits can effectively disconnect themselves from the rest of the circuit (they provide “high impedance” values to the rest of the circuit). Example: subcircuits with open collector or tri-state outputs.

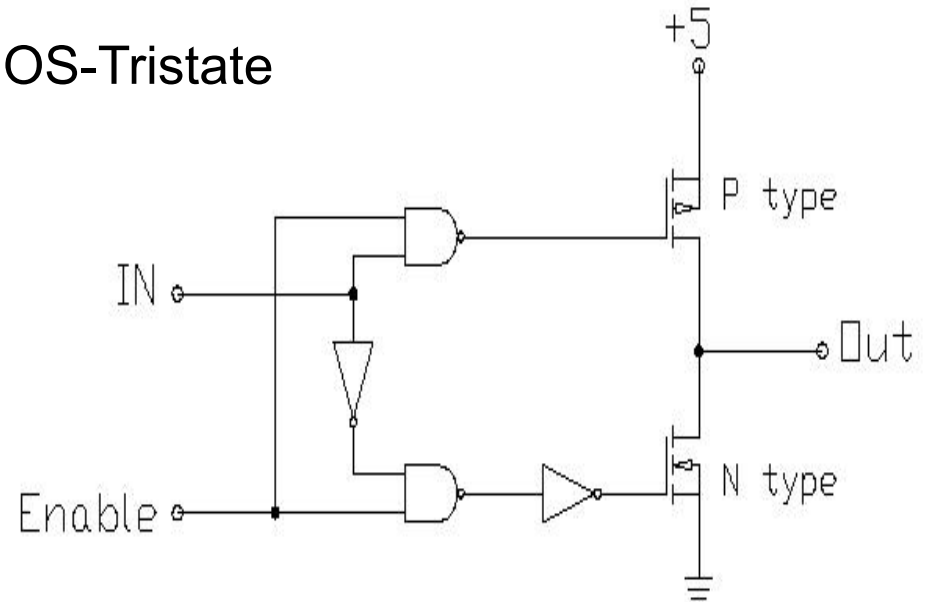

TriState circuits

nMOS-Tristate

enable = '0' -> A disconnected

CMOS-Tristate

Source: <http://www-unix.oit.umass.edu/~phys532/lecture3.pdf>

☞ We introduce signal value 'Z', meaning “high impedence”

2 signal strengths (cont'ed)

We introduce an operation $\#$, which generates the effective signal value whenever two signals are connected by a wire.
 $\#('0','Z')='0'$; $\#('1','Z')='1'$; '0' and '1' are “stronger“ than 'Z'

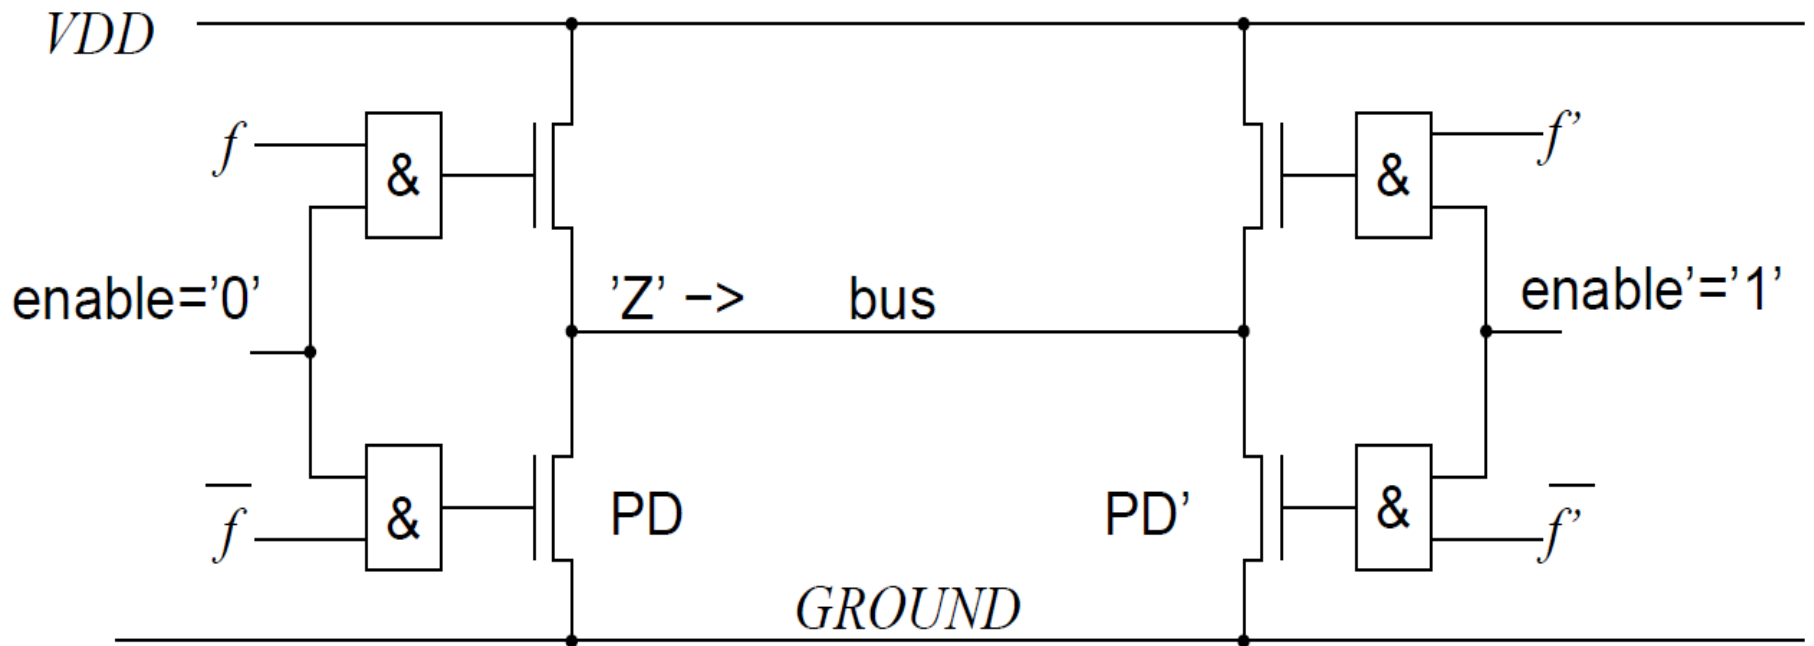

Hasse diagram

According to the partial order in the diagram, $\#$ returns the smallest element at least as large as the *two arguments* (“Sup”).

In order to define $\#('0','1')$, we introduce 'X', denoting an undefined signal level.

'X' has the same strength as '0' and '1'.

Application example

signal value on bus = $\#(\text{value from left subcircuit, value from right subcircuit})$
 $\#('Z', \text{value from right subcircuit})$
 value from right subcircuit

“as if left circuit were not there”.

IEEE 1164

VHDL allows user-defined value sets.

- ☞ Each model could use different value sets (unpractical)
- ☞ Definition of standard value set according to standard IEEE 1164:

{'0', '1', 'Z', 'X', 'H', 'L', 'W', 'U', '-'}

First seven values as discussed previously.

- ☞: Everything said about 7-valued logic applies.
- ☞: Combination of pre-charging and depletion transistors cannot be described in IEEE 1164.

'U': un-initialized signal; used by simulator to initialize all not explicitly initialized signals.

Input don't care

' - ' denotes **input don't care**.

Suppose:

$f(a,b,c) = a\bar{b} + bc$ except for $a=b=c='0'$ where f is undefined

Then, we could like specifying this in VHDL as

```
f <= select a & b & c
```

```
  '1' when "10-"  -- first term
```

```
  '1' when "-11"  -- second term
```

```
  'X' when "000"  -- 'X'  $\triangleq$  ('0' or '1') here (output don't care)
```

```
  '0' otherwise;
```

Simulator would check if $a \& b \& c = "10-"$, i.e. if $c='-'$.

Since c is never assigned a value of '-', this test would always fail. Simulator does not know that '-' means either '1' or '0', since it does not include any special handling for '-', (at least not for pre-VHDL'2006).

Function `std_match`

Special meaning of ' - ' can be used in special function `std_match`.

`if std_match(a&b&c,"10-")`
is true for any value of **c**, but this does not enable the use of the compact **select** statement.

-  The flexibility of VHDL comes at the price of less convenient specifications of Boolean functions.

VHDL'2006 has changed this: ' - ' can be used in the “intended” way in case selectors

Outputs tied together

In hardware, connected outputs can be used:

Resolution function
used for assignments to
bus, if bus is declared
as `std_logic`.

Modeling in VHDL: resolution functions

```
type std_ulogic is ('U', 'X', '0', '1', 'Z', 'W', 'l', 'h', '-');
```

```
subtype std_logic is resolved std_ulogic;
```

```
-- involve function resolved for assignments to std_logic
```

Resolution function for IEEE 1164

```
type std_ulogic_vector is array(natural range<>)of std_ulogic;
```

```
function resolved (s:std_ulogic_vector) return ...
```

```
variable result: std_ulogic:='Z'; --weakest value is default
```

```
begin
```

```
  if (s'length=1) then return s(s'low) --no resolution
```

```
  else for i in s'range loop
```

```
    result:=resolution_table(result,s(i))
```

```
  end loop
```

```
  end if;
```

```
  return result;
```

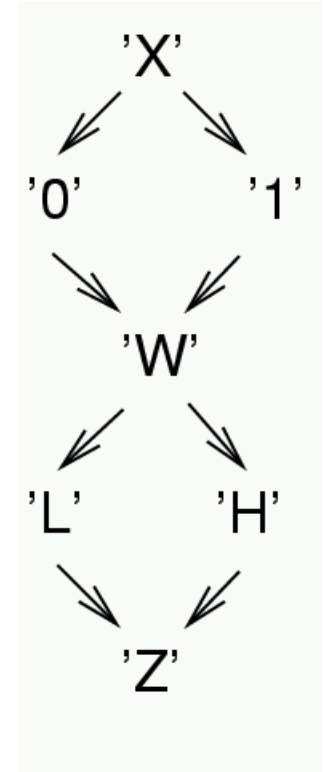

```
end resolved;
```

Using # (=sup) in resolution functions

```

constant resolution_table : stdlogic_table := (
--U  X  0  1  Z  W  L  H  -
('U', 'U', 'U', 'U', 'U', 'U',  'U', 'U', 'U'),  --| U |
('U', 'X', 'X', 'X', 'X', 'X',  'X', 'X', 'X'),  --| X |
('U', 'X', '0', 'X', '0', '0',  '0', '0', 'X'),  --| 0 |
('U', 'X', 'X', '1', '1', '1',  '1', '1', 'X'),  --| 1 |
('U', 'X', '0', '1', 'Z', 'W',  'L', 'H', 'X'),  --| Z |
('U', 'X', '0', '1', 'W', 'W',  'W', 'H', 'X'),  --| W |
('U', 'X', '0', '1', 'L', 'W',  'L', 'W', 'X'),  --| L |
('U', 'X', '0', '1', 'H', 'W',  'W', 'H', 'X'),  --| H |
('U', 'X', 'X', 'X', 'X', 'X',  'X', 'X', 'X')  --| - |
);

```

This table would be difficult to understand without the partial order

Summary

Discrete event models

- Queue of future events, fetch and execute cycle, commonly used in HDLs
- processes model HW concurrency
- signals model communication
- **wait**, sensitivity lists
- the VHDL simulation cycle
 - ▽ δ cycles, determinate simulation

Multiple-valued logic

- General CSA approach
- Application to IEEE 1164
